Abstract

We propose adding a step parameter to `iota_view`.

Proposal

We propose adding a step parameter to `iota_view` such that

- `views::iota` can generate increasing values with an increment different than 1
- `views::iota` can generate decreasing values, by the mean of a negative increment (-1 or arbitrary integral value)

```
view::iota(0, 10, 2); // [0, 4, 6, 8]
view::iota(10, 0, -2); // [10, 8, 6, 4, 2]
view::iota(0, unreachable_t{}, -1) | views::take(5); // [0, -1, -2, -3, -4]
```

Motivation

I suggested including a step parameter to `iota_view` in Belfast while discussing P1894 [?]. This would allow `views::iota` to offer a feature set equivalent to that of Python's `range` function.

It is notably useful to iterate over interlaced data such as matrices, images or audio signals. It can also be used to implements counters, paging and any other use case requiring linear sequences. That feature has been requested in `Range-v3` [?].

However, `iota_view` can be expressed in terms of `view::stride` [?] and `views::reverse`. While `iota_view` can be more efficient (and less verbose) than combining multiple views, a combination of `views::stride` and `views::enumerate` should be preferred over using `iota_view` when iterating over a container.

As such, despite the relative simplicity of the proposal and the general usefulness of the feature demonstrated by other languages and libraries, it is unclear that the cost/benefit ratio of the present proposal plays in its favor. In any case, `view::stride` [?] or something similar [?] should be prioritized over the present proposal.

Implementation

An implementation is available <https://github.com/ericniebler/range-v3/pull/1392>

Wording

No wording is provided at this time, the paper intends to gauge interest.
