views::enumerate

Document #: P2164R9
Date: 2023-05-05

Programming Language C++

Audience: LEWG, LWG

Reply-to: Corentin Jabot <corentin.jabot@gmail.com>

A struct with 2 members, how hard can it be?!

Abstract

We propose a view enumerate whose value type is a struct with 2 members index and value representing respectively the position and value of the elements in the adapted range.

Revisions

R9

Wording fixes

- Introduce *range-with-movable-references* to ensure the reference type of the underlying type can be moved.
- Remove enumerate_view::iterator::index_type and use difference_type everywhere. LEWG felt strongly neutral about index_type in Kona and LWG did not like it.
- operator<=> returns strong_ordering (always operate on ints).
- Ensure constructors don't brace initialize.
- Fix iter_swap' noexcept specification.
- Add missing constraint on enumerate_view::end().
- iterator::base() now returns a const reference and is not constrained
- Attempt at improving the ackward formatting.
- Other small editorial fixups.

R8

- remove the wording for enumerate result following SG9 consensus to use std::tuple.
- Qualify std::move

- Italicize base_ and simple-view
- Unconditionally use range_difference_type as the index_type
- Model the sentinel wording on elements_view in order to support mixed comparison
- Add missing explicit on the one parameter constructor
- Improve the specification of the begin/end methods
- Add missing enable_borrowed_range specialization
- Greatly simplify the comparison operators
- Propose an index methods to avoid deferencing the underlying iterator when not needed.
 The * operator of the underlying range might be expensive, if the user only cares about the index, the index method could be used to query the index cheaply in all cases. It is trivial to specify, implement, and could be provided later at no cost. But I'm happy to do that change if it increases consensus.
- · Other minor wording fixes.

R7

- This version asks LEWG to choose between tuple or enumerate_result as the reference and value types of enumerate_view. The approach presented in previous revisions of having a value type and a reference type of different types proved not workable. We need to pick one of the two options. Wording is provided for both.
- Add missing iter_move and iter_swap functions.
- Add the markup for freestanding
- Add feature test macro
- Formatting fixes.

R6

Wording changes:

- Add enumerate_result to the list of tuple-like types
- Because enumerate_view::iterator::operator*returns values, enumerate_view::iterator cannot be a Cpp17ForwardIterator. Change iterator_category and add iterator_concept accordingly.

R5

Instead of adding complexity to enumerate_result, we assume changes made by P2165R2 [1]. P2165R2 [1] makes pair constructible from *pair-like* objects, and associative containers deduction guides work with ranges of *pair-like* objects. With these changes, enumerate_result

can remain a simple aggregate. We just need to implement the tuple protocol for it (get, tuple_element, tuple_size).

P2165R2 [1] ensures a common reference exists between enumerate_result and std::tuple as long as one exists between each element.

count_type is renamed to index_type. I am not sure why I ever chosed count_type as the initial name.

R4

This revision is intended to illustrate the effort necessary to support named fields for index and value. In previous revisions, the value and reference types were identical, a regrettable blunder that made the wording and implementation efforts smaller than they are. reference and value_type types however needs to be different, if only to make the ranges::to presented in this very paper.

If that direction is acceptable, better wording will be provided to account for these new reference and value_type types.

This revision also gets rid of the const index value as LEWG strongly agreed that it was a terrible idea to begin with, one that would make composition with other views cumbersome.

R3

Typos and minor wording improvements

R2, following mailing list reviews

- Make value_type different from reference to match other views
- Remove inconsistencies between the wording and the description
- Add relevant includes and namespaces to the examples

R1

Fix the index type

Tony tables

Before

After

#include <ranges>

std::vector days{"Mon", "Tue",
 "Wed", "Thu", "Fri", "Sat", "Sun"};

int idx = 0;
for(const auto & d : days) {

for(const auto & [index, value]

#include <ranges>

#include <ranges>

std::vector days{"Mon", "Tue",
 "Wed", "Thu", "Fri", "Sat", "Sun"};

int idx = 0;
for(const auto & [index, value]

}

: std::views::enumerate(days)) {

print("{} {} \n", index, value);

Motivation

idx++;

}

print("{} {} \n", idx, d);

The impossibility to extract an index from a range-based for loop leads to the use of non-range-based for loops, or the introduction of a variable in the outer scope. This is both more verbose and error-prone: in the example above, the type of idx is incorrect.

enumerate is a library solution solving this problem, enabling the use of range-based for loops in more cases.

It also composes nicely with other range facilities: The following creates a map from a vector using the position of each element as key.

```
my_vector | views::enumerate | ranges::to<map>;
```

This feature exists in some form in Python, Rust, Go (backed into the language), and in many C++ libraries: ranges-v3, folly, boost::ranges (indexed).

The existence of this feature or lack thereof is the subject of recurring StackOverflow questions.

Design

std::tuple vs aggregate with name members

Following the trend of using meaningful names instead of returning pairs or tuples, one option is to use a struct with named public members.

```
struct enumerate_result {
    count index;
    T value;
};
```

This design was previously discussed by LEWGI in Belfast in the context of P1894R0 [4], and many people have expressed a desire for such struct with names.

```
std::vector<double> v;
enumerate(view) | to<std::vector>(); // std::vector<std::tuple<std::size_t, double>>.
enumerate(view) | to<std::map>(); // std::map<std::size_t, double>.
```

Why not just always return a tuple and rely on structure binding?

If a range reference type is convertible to the index type, it is error-prone whether one should write

```
for(auto && [value, index] : view | std::views::enumerate)
for(auto && [index, value] : view | std::views::enumerate)
```

Having named members avoids this issue. The feedback I keep getting is "we should use a struct if we can". Which is consistent with previous LEWG guidelines to avoid using pair when a more meaningful type is possible.

Why use a tuple?

The drawback of using a distinct type is that

```
auto vec = enumerate(view) | ranges::to<std::vector>();
```

would produce a vector<enumerate_result<std::size_t, range_value_t<decltype(view)>>
where ideally, I think it should produce a tuple.

Why not enumerate_result as reference type and tuple as value type?

This was the approached proposed by the previous revision of the paper and my preferred solution. Best of both world. It only has a smal drawback: it doesn't work.

Many algorithms end up requiring invocable<F&, iter_value_t<I>&> && invocable<F&, iter_reference_t<I>>> (where F is a function), which would require std::tuple<std::size_t, Foo>& to be convertible to enumerate_result<std::size_t, Foo>.

In practice, this means that many algorithms are not utilisable if reference and values are not the same type

```
std::ranges:::find(enumerate(/*...*/), [](auto const& p) { // constraints not satisfied.
    return /*...*/;
})
```

This is simply not acceptable.

Tomasz also observed that it would interract pourly with as_const.

```
for (auto const& p : enumerate(/*...*/)) {
    something(p.value); // OK
}

for (auto const& p : enumerate(/*...*/) | views|as_const) {
    something(p.value); // KO decltype(p) is tuple<std::size_t, const Foo&>
}
```

Which is... not great. The unfortunate invocable<F&, iter_value_t<I>&> constraints exists as some algorithms (not find) may constructs value types out of the elements of the range.

Where do we go from here?

We need to choose between using tuple or enumerate_result, and that type would be used for both the value type and the reference type.

POLL: Does LEWG prefer using enumerate_result (Option 1) rather than a tuple (Option 2) as the value and reference type of enumerate_view::iterator?

The wording provides both options.

Why not zip(iota, view)?

Zipping the view with iota does not actually work (see also P2214R0 [3]), and a custom index_-view would need to be used as the first range composed with zip, so a custom enumerate view with appropriately named members is not adding a lot of work.

enumerate as presented here is slightly less work for the compiler, but both solutions generate similar assembly.

Performance

An optimizing compiler can generate the same machine code for views::enumerate as it would for an equivalent for loop. Compiler Explorer [Editor's note: This implementation is a prototype not fully reflective of the proposed design].

Implementation

This proposal has been implemented (Github) There exist an implementation in ranges-v3 (where the enumerate view uses zip_with and a pair value type).

Proposal

We propose a view enumerate whose value type is a struct with 2 members index and value representing respectively the position and value of the elements in the adapted range.

Wording

Header < ranges > synopsis

[ranges.syn]

```
template<class R>
using keys_view = elements_view<R, 0>;  // freestanding
template<class R>
using values_view = elements_view<R, 1>;  // freestanding
namespace views {
```

```
template<size_t N>
    inline constexpr unspecified elements = unspecified; // freestanding
    inline constexpr auto keys = elements<0>;
                                                          // freestanding
    inline constexpr auto values = elements<1>;
                                                          // freestanding
}
template<input_range View>
requires view<View>
class enumerate_view; // freestanding
template<class View>
inline constexpr bool enable_borrowed_range<enumerate_view<View>> = // freestanding
enable_borrowed_range<View>;
namespace views { inline constexpr unspecified enumerate = unspecified; } // freestanding
// ??, zip view
template<input_range... Views>
requires (view<Views> && ...) && (sizeof...(Views) > 0)
                                                         // freestanding
class zip_view;
template<class... Views>
inline constexpr bool enable_borrowed_range<zip_view<Views...>> = // freestanding
(enable_borrowed_range<Views> && ...);
namespace views { inline constexpr unspecified zip = unspecified; } // freestanding
[...]
}
```

Helper concepts

[range.utility.helpers]

Many of the types in subclause **??** are specified in terms of the following exposition-only concepts:

[Editor's note: The intent is that this concept can be reused by LWG3731 [2]]

```
template <class R>
concept range-with-movable-references = // exposition only
input_range<R> && move_constructible<range_reference_t<R>> &&
move_constructible<range_rvalue_reference_t<R>>;
```

[Editor's note: Add the following new section before [range.zip]]

Enumerate view

[range.enumerate]

Overview

[range.enumerate.overview]

enumerate_view is a view whose elements represent both the position and value from a sequence of elements.

The name views::enumerate denotes a range adaptor object[range.adaptor.object]. Given a subexpression E, the expression views::enumerate(E) is expression-equivalent to enumerate_view<views::all_t<decltype((E))>>(E).

[Example:

```
vector<int> vec{ 1, 2, 3 };
for (auto [index, value] : enumerate(vec) )
    cout << index << ":" << value << ' '; // prints: 0:1 1:2 2:3

— end example]</pre>
```

Class template enumerate_view

[range.enumerate.view]

```
template<view V>
requires range-with-movable-references<V>
class enumerate_view : public view_interface<enumerate_view<V>> {
    V base_ = V(); // exposition only
    template<bool Const>
    class iterator; // exposition only
    template<bool Const>
    class sentinel; // exposition only

public:
    constexpr enumerate_view() requires default_initializable<V> = default;
    constexpr explicit enumerate_view(V base);

constexpr auto begin() requires (!simple-view<V>)
    { return iterator<false>(ranges::begin(base_), 0); }

constexpr auto begin() const requires range-with-movable-references<const V>
    { return iterator<true>(ranges::begin(base_), 0); }
```

```
constexpr auto end() requires (!simple-view<V>) {
          if constexpr (common_range<V> && sized_range<V>)
                return iterator<false>(ranges::end(base_), ranges::distance(base_));
         else
                return sentinel<false>(ranges::end(base_));
         }
        constexpr auto end() const requires range-with-movable-references<const V> {
          if constexpr (common_range<const V> && sized_range<const V>)
            return iterator<true>(ranges::end(base_), ranges::distance(base_));
            return sentinel<true>(ranges::end(base_));
        }
        constexpr auto size()
        requires sized_range<V>
        { return ranges::size(base_); }
        constexpr auto size() const
        requires sized_range<const V>
        { return ranges::size(base_); }
        constexpr V base() const & requires copy_constructible<V> { return base_; }
        constexpr V base() && { return std::move(base_); }
    };
    template<class R>
    enumerate_view(R&&) -> enumerate_view<views::all_t<R>>;
}
    constexpr explicit enumerate_view(V base);
     Effects: Initializes base_ with std::move(base).
```

Class enumerate_view::iterator

[range.enumerate.iterator]

```
namespace std::ranges {
    template<view V>
    requires range-with-movable-references<V>
    template<bool Const>
    class enumerate_view<V>::iterator {
        using Base = maybe-const<Const, V>; // exposition only
    public:
        using iterator_category = input_iterator_tag;
        using iterator_concept = see below;
        using difference_type = range_difference_t<Base>;
        using value_type = tuple<difference_type, range_value_t<Base>>;
    private:
        using reference-type = // exposition only
```

```
tuple<difference_type, range_reference_t<Base>>;
    iterator_t<Base> current_ = iterator_t<Base>(); // exposition only
   difference_type pos_ = 0; // exposition only
   constexpr explicit
    iterator(iterator_t<Base> current,
             difference_type pos); // exposition only
public:
    iterator() requires default_initializable<iterator_t<Base>> = default;
    constexpr iterator(iterator<!Const> i)
    requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;
    constexpr const iterator_t<Base> & base() const & noexcept;
    constexpr iterator_t<Base> base() &&;
    constexpr difference_type index() const noexcept;
    constexpr auto operator*() const {
        return reference-type(pos_, *current_);
   constexpr iterator& operator++();
   constexpr void operator++(int);
   constexpr iterator operator++(int) requires forward_range<Base>;
    constexpr iterator& operator--() requires bidirectional_range<Base>;
    constexpr iterator operator--(int) requires bidirectional_range<Base>;
    constexpr iterator& operator+=(difference_type x)
    requires random_access_range<Base>;
    constexpr iterator& operator==(difference_type x)
    requires random_access_range<Base>;
   constexpr auto operator[](difference_type n) const
    requires random_access_range<Base>
    { return reference-type(pos_ + n, current_[n]); }
   friend constexpr bool operator==(const iterator& x, const iterator& y) noexcept;
    friend constexpr strong_ordering operator<=>(const iterator& x, const iterator& y)
noexcept;
    friend constexpr iterator operator+(const iterator& x, difference_type y)
    requires random_access_range<Base>;
    friend constexpr iterator operator+(difference_type x, const iterator& y)
    requires random_access_range<Base>;
    friend constexpr iterator operator-(const iterator& x, difference_type y)
    requires random_access_range<Base>;
    friend constexpr difference_type operator-(const iterator& x, const iterator& y);
```

The member *typedef-name iterator*::iterator_concept is defined as follows:

- If Base models random_access_range, then iterator_concept denotes random_access_iterator_tag.
- Otherwise, if Base models bidirectional_range, then iterator_concept denotes bidirectional_-iterator_tag.
- Otherwise, if Base models forward_range, then iterator_concept denotes forward_iterator_tag.
- Otherwise, iterator_concept denotes input_iterator_tag.

```
constexpr explicit iterator(iterator_t<Base> current, difference_type pos = 0);
     Effects: Initializes current_ with std::move(current) and pos_ with pos.
    constexpr iterator(iterator<!Const> i)
    requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;
     Effects: Initializes current_ with std::move(i.current_) and pos_ with i.pos_.
    constexpr const iterator_t<Base> & base() const & noexcept;
